

The Little Guy Machine: Cognitive-Composition Audit

THE LITTLE GUY MACHINE

A Cognitive-Composition Audit: How It Thinks, How It Builds Music, and Where the Weirdness Actually Comes From

Prepared: 2026-09-22

Scope: merrypranxter/my_lil_guys_for_suno, plus the supplied Little Guy run exports and the *Temporary Minds* — 26 Standalone Cognitive Installation Prompts library.

Purpose: A fast but broad technical/creative map that can be fed into another generative “weird guy” so it can mutate the underlying methods rather than merely copy the resulting style.

Abstract

The Little Guy Machine is not fundamentally a genre blender. Its real invention is a **modular cognitive composition architecture**.

The machine separates two problems that most music prompting collapses together:

1. **How should the system think?**
2. **What musical materials should that thinking act upon?**

The first problem is handled by thirteen “Little Guys,” each representing a distinct cognitive mutation: semantic recoil, invented emotion, wrong classification, reverse causality, property transfer, primitive deletion, alien sensing, lossy cognition, bureaucratic narration, reconstructive memory, literal identity collapse, coherent false premises, and observational emergence.

The second problem is handled by an eight-axis musical fingerprint: genre/performance family, harmony, melody, rhythm, timbre, vocal system, performance behavior, and production method.

The system then refuses to dissolve these ingredients into a single vague hybrid. Instead, it gives them **separate jurisdictions** and forces them to negotiate. Harmony does harmony. Rhythm does rhythm. A cognitive operator may govern causality while another governs memory and another governs narration. The composition stays legible because an **anchor/invariant** survives while other properties mutate.

The result is a machine for creating **structured incompatibility** rather than random novelty.

Its strongest principle can be summarized as:

Do not blend strange ingredients. Assign them different jobs, preserve their incompatibility, and make the composition survive the argument.

This audit finds that the machine's most interesting behavior comes from five interacting design ideas:

- cognitive rules are treated as causal laws rather than themes;
- musical dimensions are independently controlled rather than genre-blended;
- mutation occurs against a preserved invariant;
- past outputs are remembered as territory to avoid and as mechanisms to learn from;
- formal weirdness is enacted by rhythm, phonetics, structure, repetition, and causal transformation, not merely described in lyrics.

The supplied runs show that the same seed and nearly the same Little Guy stack can yield bluegrass/swing, ragtime/vaudeville, garage-rock/gospel, jazz-fusion/bebop, and funk-inflected music-hall results while preserving a recognizable conceptual logic. That is important: **the cognitive identity is more stable than the genre identity.**

1. The Core Design Philosophy

The machine repeatedly distinguishes **operational weirdness** from decorative weirdness.

Decorative weirdness says:

“Make it surreal, chaotic, strange, cosmic, experimental.”

Operational weirdness says:

“Fix one thing. Mutate another. Give a third system authority over a different variable. Force the contradiction to remain active. Show the listener the consequences.”

That distinction is the backbone of the whole system.

The master generation prompt explicitly rejects “generic weirdness salad” and instructs the model to treat cognitive rules as **physical laws**. Musical traditions are likewise treated as **rule systems**, not as aesthetic labels.

That means “gospel + punk + ragtime” is not the target. A stronger construction would be something like:

- gospel owns harmonic release,
- punk owns rhythmic interruption,
- ragtime owns subdivision,
- bureaucratic narration owns semantic tone,
- a three-note figure remains invariant,
- every return of that figure carries one scar from the previous section.

This is substantially different from fusion-by-adjective. It is closer to designing a small artificial universe.

2. The Thirteen-Jurisdiction Cognitive Basis

One of the most elegant patterns in the repository is easy to miss:

There are thirteen Little Guys and thirteen default cognitive jurisdictions, and each jurisdiction is represented exactly once.

The jurisdictions are:

semantic meaning, memory, causality, attention, narration, representation, classification, temporal structure, emotional weighting, observation, information loss, ontology, and lyric syntax.

This makes the Little Guy collection behave like a **basis set of cognitive deformations**. They are not merely thirteen personalities. Each attacks a different layer of the generative process.

When stacked, they are less likely to cancel each other because they are intended to operate on different variables.

3. Full Little Guy Audit

Little Guy	Cognitive operation	Default jurisdiction	What it changes in a composition
RETCON RAT — Semantic Recoil	Later information retroactively changes the active meaning of earlier information. The old meaning is not restored.	semantic meaning	A repeated lyric, hook, chord, or event can return unchanged acoustically but mean something different because later material has altered its context. This enables genuine retroactive form rather than simple reprise.
EMOTION CRYPTID — Invented Emotion	Defines a non-human affect using a trigger, detector, intensity rule,	emotional weighting	The song can be selected and developed according to an alien emotional

Little Guy	Cognitive operation	Default jurisdiction	What it changes in a composition
	attraction/avoidance behavior, and consequences for attention and memory.		utility system rather than standard sad/happy/tense/released categories.
TAXONOMY GOBLIN — Wrong Classification	Finds a coherent wrong category and constructs the world in which that classification is literally correct.	classification	The subject is not “like” something else; it is treated as a different class of thing, and the musical/lyrical consequences must follow rigorously.
FUTURE BASTARD — Causal Backfill	Fixes a terminal event first and reasons backward to determine what earlier states must exist.	temporal structure	The ending can become a boundary condition. Earlier motifs, instrumentation, absences, or rhythmic events exist because the final state requires them as ancestors.
PROPERTY THIEF — Ownership Transfer	Removes a property from its normal owner and gives it literally to an unexpected host.	representation	Musical properties can migrate across dimensions: silence may “own” syncopation, lyrics may “own” percussion, tuning may become a property of spatial production, etc. The point is not metaphor but changed behavior.
HOLE GUY — Missing Primitive	Deletes one foundational concept without replacement and forbids proxies.	information loss	A song can be rebuilt after removing a supposedly necessary primitive: beat, refrain, stable pitch center, narrator, ownership of melody,

Little Guy	Cognitive operation	Default jurisdiction	What it changes in a composition
			ordinary word identity, or another load-bearing element. The vacancy itself becomes causal.
SENSORY FREAK — Alien Sensorium	Invents a sense for an abstract property, defines its encoding, and defines a reflex to the signal.	observation	Contradiction, causal debt, semantic instability, probability, forgotten obligations, or another abstract quantity can become “sensed” and trigger concrete musical changes.
JPEG BRAIN — Lossy Cognition	Compresses an idea until meaningful distinctions disappear, finds collisions, then reconstructs without recovering the lost information.	lyric syntax	Language can quantize, alias, fragment, or collapse unrelated concepts into the same phonetic/semantic encoding. The artifacts are structural consequences of missing information.
COSMIC CLERK — Administrative Impossible	Describes impossible events using routine procedural, clerical, regulatory, maintenance, or technical language.	narration	Creates deadpan semantic friction: cosmic collapse is narrated as a filing problem. The music can intensify absurdly while the narrator refuses awe.
RECALL MOLD — Reconstructive Memory	Every recall is altered by the context in which it is recalled; the altered memory becomes the next remembered version.	memory	Repeated hooks, motifs, stories, or sonic objects mutate cumulatively. The fourth return remembers the scarred third return, not the pristine first.
IDENTITY	Asserts literal	ontology	Musical roles can

Little Guy	Cognitive operation	Default jurisdiction	What it changes in a composition
ACCIDENT — A Is Literally B	identity between incompatible entities and continues reasoning precisely without turning the relation into metaphor.		collapse: the chorus is the tempo; the singer is the room; the cadence is the narrator; the snare is literally the missing lyric. The point is to change permitted operations.
CONFIDENT MACHINE — Coherent Wrong Premise	Adopts one subtle false assumption and rigorously develops a complete theory without correcting it.	causality	A song can behave like a proof whose initial axiom is wrong. Every later event becomes coherent locally while the global theory grows increasingly alien.
OBSERVATION LOG — Unannounced Emergence	Reports dry measurements while behavior gradually exceeds the explanatory power of the original model.	attention	Transformation is shown through telemetry rather than announced. A phase change can emerge because measurements stop fitting the initial category.

The important feature is that these are **not merely lyric-writing gimmicks**. The system explicitly tells the generator that a Little Guy must alter logic and causal structure.

4. Stack Logic: Primary World + Secondary Pressure

Order matters.

The first Little Guy is the **primary generative foundation**. It establishes the ontology, baseline mechanics, and structural world.

Every later Little Guy becomes a **mutator or regulator**. It is instructed to constrain, damage, invert, pressure, or mutate the primary system **without erasing it**.

This is a clever alternative to averaging.

If three creative rules are simply blended, the output often collapses toward the statistical middle. The Little Guy stack instead preserves asymmetry:

Primary rule: “This is the world.”

Secondary rule: “Fine. But memory now works differently.”

Third rule: “Fine. But narration is bureaucratic.”

Fourth rule: “Fine. But observations detect causal debt.”

The resulting work is produced at the seam between rules.

The interface reinforces this explicitly: “Order matters. Primary guy establishes ontology; secondary guys constrain and mutate.”

The normal random-stack control selects two to four Guys. The “FUCK ME UP” mode is designed for three to five divergent Guys and therefore increases cognitive friction.

Because every Guy already owns a different default jurisdiction, even a random selection naturally tends to produce orthogonal pressures.

5. The Musical Fingerprint: Eight Independent Composition Axes

The cognitive system does not choose music as one monolithic genre label. It constructs a fingerprint across eight separate musical axes:

1. **Genre/performance family**
2. **Harmony**
3. **Melody**
4. **Rhythm**
5. **Timbre**
6. **Vocal behavior**
7. **Performance attitude**
8. **Production**

This is one of the most important things to steal from the machine.

Instead of asking “What genre is this?”, it asks:

What ancestry governs the ensemble?
What independent system governs chord behavior?
What governs contour?
What governs time?
What governs material/texture?
What does the mouth do?
How do the performers behave?
What kind of recorded space makes this object exist?

The current taxonomy contains:

- **24** genre/performance families
- **14** harmonic systems
- **12** melodic systems
- **15** rhythmic systems
- **13** timbral systems
- **15** vocal systems
- **10** performance attitudes
- **12** production systems

The raw cross-product is approximately **1.415 billion possible musical fingerprints** before Little Guy order, seed, energy, formal operators, anchors, or model variation are considered.

The important part is not the huge number by itself. The important part is that the coordinates remain separately addressable.

6. Musical Ancestries Available to the Machine

The genre/performance-family library deliberately ranges across very different performance cultures:

funk and soul band language; garage rock and proto-punk abrasion; doo-wop and vocal-group pop; glam and theatrical rock; psychedelic pop and acid-folk color; cabaret/vaudeville/music-hall staging; gospel ensemble singing; bluegrass and old-time string band; surf/twang instrumental rock; disco/live dance-band propulsion; house repetition; jungle/breakbeat science; electro/machine-funk; art-rock/angular post-punk; chanson; orchestral bombast; marching-band mechanics; lounge/exotica/novelty arrangement; folk-dance/communal song; jazz-combo interaction; raga-informed development; Latin/clave-centered ensemble logic; minimalist phase process; and industrial/abrasive electronic music.

The library is intentionally broad enough to prevent “experimental” from silently meaning “glitchy electronic industrial stuff again.”

That anti-default stance appears explicitly in the master prompt.

7. Harmonic Thinking

The harmonic library is also heterogeneous. It includes:

- close-position vocal harmony with contrary inner motion;
- functional tonality with chromatic side-steps;
- quartal voicings and suspended fields;
- modal drones;

- overtone/spectral chord derivation;
- blues-dominant instability;
- parallel block triads;
- gospel extensions with delayed cadence;
- barbershop voice leading and ringing dominant tension;
- whole-tone and augmented symmetry;
- microtonal pure intervals against equal-tempered accompaniment;
- pedal tones with rotating upper structures;
- simultaneous bitonal centers;
- diatonic sweetness interrupted by non-diatonic clusters.

The key idea is again jurisdiction. Harmony controls **tension, voicing, chord motion, consonance, dissonance, and tonal organization**, but it does not automatically dictate rhythm, melody, or affect.

8. Melodic Thinking

The melodic library includes several fundamentally different concepts of “melody”:

- fast scat-derived contour;
- long melismatic arcs that ignore bar lines;
- raga-like hierarchy, ornament, slides, and turns;
- yodel register flips;
- whistled melody imperfectly doubled by another voice;
- narrow angular punk cells;
- folk ornament and call-and-response;
- chromatic cabaret patter opening into long vowels;
- gospel melisma answered by blunt unison hooks;
- hocketed fragments split among voices/instruments;
- retrograde returns with changed interval sizes;
- nursery-simple stepwise motifs undergoing increasingly alien decoration.

Notice how many of these are **procedures** rather than stylistic adjectives.

9. Rhythmic Thinking

The rhythmic library treats groove as a manipulable causal system:

- deep funk pocket with displaced sixteenths;
- triplet swing under straight melodic phrasing;

- footwork-speed kick logic with spacious upper layers;
- clave-centered cross-rhythm;
- motorik pulse with missing beats;
- waltz invaded by duple accents;
- additive asymmetric Balkan-style meter;
- half-time stomp with fast ornamentation;
- chopped breakbeats that preserve backbeat landmarks;
- disco four-on-the-floor with live syncopation;
- march cadence deformed by triplets;
- rubato vocal time over rigid dance time;
- 3:4 and 5:4 polyrhythmic coexistence;
- shuffle with abrupt metric compression;
- stop-start punk rhythm with hard silence.

This library already reveals one of the engine's favorite operations: **make incompatible temporal scales coexist without reconciling them.**

10. Timbre and Material Thinking

The timbral library moves among ensemble worlds rather than assuming synthesizers:

- dry drums, bass, claps, brass;
- fuzz guitar, cheap organ, tambourine, room bleed;
- upright bass, brushes, vibraphone, reeds;
- banjo, fiddle, mandolin, stomps, body percussion;
- gospel piano/organ/claps/voices;
- surf guitar, spring reverb, floor toms, tack piano;
- Balkan brass, snare, accordion, shouts;
- toy instruments, whistles, spoons, kazoo-like reeds, orchestral percussion;
- strings, harp, timpani, oversized brass;
- glass harmonica, bowed metal, prepared piano, acoustic percussion;
- analog synth bass, machine transients, vocoder fragments, hand percussion;
- sampled breaks, sub-bass, chopped vocals, digital stabs;
- industrial metal percussion, distorted electronics, tape abrasion.

The diversity mechanism specifically penalizes recently used material so this list acts more like a rotating ecology than a favorites menu.

11. The Voice Is Not “Lyrics on Top”

The machine treats the voice as another compositional instrument.

Its vocal systems include:

deadpan narration, percussion-like scat, doo-wop vocables, operatic recitative, yodel register fracture, solo/ensemble call-and-response, polyphony with independent lyric timing, near-spoken patter, whispered ensemble pulse under full voice, falsetto and whistle-register punctuation, vowel melisma with consonants reserved for downbeats, nasal drone singing, hocketed syllables, overtone-rich sustain, and ululation/rolled consonants.

It then adds a **phonetic engine**:

- hard consonants = transients/percussion;
- nasals = resonance/drone;
- open vowels = sustained melody;
- rolled consonants = acceleration/agitation;
- dense syllables = temporal compression;
- long vowels = stretched time;
- heavy syllables = bass weight.

This is a major conceptual move.

The text is not only semantic content. **The physical mouth becomes a control surface for time, texture, impact, and pitch behavior.**

A nonsense syllable therefore does not need to “mean” anything if it is doing compositional work.

12. Performance and Production Are Separate Systems Too

Performance attitude includes states such as:

ecstatic physical commitment, deadpan precision against absurd arrangement, dance-floor swagger, theatrical overstatement played straight, communal urgency, reckless garage energy with disciplined timing, hyper-articulate nervousness, competitive joyful call-and-response, ceremonial grandeur applied to trivial material, and sweet earnestness against hostile accompaniment.

Production is separately controlled through options such as:

mono room bleed, dry 1970s studio recording, cassette saturation, glossy wide 1980s stereo, transistor-radio contrast, pristine modern close-miking, live-club room reflections, dub-style spatial throws, uneven bedroom gain staging, orchestral-stage perspective, hard digital editing over acoustic sources, and industrial tape/metal processing.

Again: a performance can be ecstatic while the recording is clinically dry. A ridiculous text can receive ceremonial grandeur. A garage band can be recorded with absurd modern precision.

The contradiction is preserved because each layer owns a different job.

13. The Anchor / Invariant

The machine nearly always creates one recognizable element that survives mutation.

The procedural engine defaults to a short three-note or three-syllable figure.

The anchor is important because completely unconstrained mutation becomes noise. An invariant gives the listener a measuring stick.

The more the surrounding music mutates, the more useful the anchor becomes.

Then the system introduces an especially productive rule:

the anchor may return **recognizable but scarred**.

This means continuity does not require pristine repetition.

A return can preserve contour but change one interval.

A lyric can preserve syntax but lose one word.

A rhythm can preserve landmark accents but change subdivision.

A timbre can preserve a phrase while its material substrate changes.

The anchor becomes a memory object with mutation history.

14. The Core Operator Family

The master prompt asks for five to ten transformations rather than vague moods. Its recurring operator grammar includes:

Hold A fixed while B migrates.

One variable becomes the measuring instrument for another variable's change.

Compress X while stretching Y.

Two temporal scales diverge.

Make A behave like B without becoming B.

Functional transfer occurs without identity collapse.

Preserve X while destabilizing everything around it.

A local invariant creates global perceptual contrast.

Force incompatible temporal scales to coexist.

Rather than alternating between systems, simultaneous disagreement is maintained.

Return to the anchor in a more mutated form.

Recurrence accumulates history instead of resetting.

These operators are reusable beyond music. They are essentially a miniature language for creating transformations under constraint.

15. Macro-Form as a Mutation Cycle

The preferred large-scale form is:

FORM – DESTABILIZE – FRACTURE – COLLAPSE – ANCHOR RETURNS – REFORM STRANGER

This is not simply a dramatic arc. Each stage has a functional job.

FORM

Establish a legible specimen. The listener needs to know what “normal” is before mutation becomes measurable.

DESTABILIZE

Independent jurisdictions begin disagreeing. Harmony may seek resolution while melody refuses. Rhythm may accelerate internally while the vocal line stretches.

FRACTURE

Different temporal and structural systems are forced into coexistence. The system stops behaving as one unified machine.

COLLAPSE

Support is removed rather than simply making everything louder. A jurisdiction can temporarily disappear. The composition discovers which relationships were load-bearing.

ANCHOR RETURNS

The invariant reappears and reveals what changed.

REFORM STRANGER

The opening is not restored. Useful damage is incorporated into a new coherent rule set.

This is closer to **developmental biology** or **state transition** than verse/chorus form.

16. Anti-Monoculture Memory

The machine keeps musical fingerprints from recent runs.

Those fingerprints become **negative memory**: territory already explored.

The master prompt tells the generator to move toward genuinely different ancestry instead of swapping synonyms. It even contains a specific anti-default rule: if recent outputs have clustered around electronic, industrial, synth-heavy, glitchy, or clinical territory, the next generation should preferentially search acoustic, vocal, ensemble, folk, dance-band, rock, theatrical, orchestral, communal, or other contrasting systems.

This is not simply randomization.

Randomness can repeatedly choose neighboring ideas.

The machine instead tries to model novelty as **distance from recent occupied territory**.

The procedural fallback implements a simpler version by penalizing musical taxonomy items whose identifying phrase already appears in recent fingerprints.

17. Positive Memory: Stars and Feedback

Negative memory says, “We have already been here.”

Positive memory says, “Something about this worked.”

Starred runs are turned into compact preference signals containing the stack, seed context, fingerprint, and optional user feedback.

Crucially, the master prompt says:

preserve the liked principle, not the surface copy.

This is a sophisticated creative-learning rule.

If a user liked a track because the voice behaved like percussion against lush harmony, the system should not merely recreate the same genre/instrument list. It should infer the mechanism and express it through different material.

This creates the beginnings of a **mechanism-level preference model**.

18. Two Different Generators Live Inside the Machine

The system has two composition paths.

A. Model-based inference

The primary path sends the structured stack, musical history, preference signals, seed, energy, and taxonomy to a Gemini model.

The server cycles through several candidate models if one fails or times out.

The inference temperature is slightly above 1, encouraging variation while the schema and prompt provide strong structural control.

The model returns:

- style;
- lyrics/control;
- caption;
- an eight-part musical fingerprint.

B. Procedural synthesizer fallback

If AI generation is unavailable, a deterministic-ish procedural composer constructs the result directly from the taxonomy and stack.

This version is less semantically magical but much more reliable about structure and length.

It explicitly generates each macro-form stage, phonetic-engine behavior, secondary jurisdiction entries, anchor damage, and reform.

This distinction matters when studying the supplied outputs because the two engines have different strengths.

19. Precision Length as a Separate Engineering Problem

The system targets:

- STYLE: 975–999 characters
- LYRICS/CONTROL: 4900–4999 characters
- CAPTION: 490–499 characters

This is not left entirely to generation.

There is a separate repair prompt, and if model repair fails the server can algorithmically trim or pad.

That separation is architecturally sound: **creative generation and dimensional compliance are different tasks.**

The uploaded runs also demonstrate why that separation matters.

20. Empirical Audit of the Supplied Runs

Several supplied runs use nearly identical math-mania seeds and similar stacks. This is unusually useful because it acts like a small controlled experiment.

Run	Stack	Engine	Musical result
13:07:06	COSMIC CLERK → JPEG BRAIN → SENSORY FREAK	Gemini 3.1 Flash Lite	avant-garde bluegrass + swing; 7/8; resonator banjo, tack piano, upright bass; yodel/scat/patter
13:11:02	COSMIC CLERK → JPEG BRAIN → SENSORY FREAK	Gemini 3.5 Flash Lite	cabaret/vaudeville/ ragtime; 2/4; tack piano, tuba, accordion, slide whistle
13:11:33	COSMIC CLERK → JPEG BRAIN → SENSORY FREAK	Gemini 3.5 Flash Lite	garage rock + ecstatic gospel; waltz invaded by duple accents; fuzz guitar, cheap organ, gospel piano
13:13:34	JPEG BRAIN → SENSORY FREAK → COSMIC CLERK	Gemini 3.1 Flash Lite	jazz-fusion/high- speed bebop; 9/8– 5/4 against 4/4 anchor; brass, percussive piano, clinical dry mix
13:15:42	CONFIDENT MACHINE → JPEG BRAIN → SENSORY FREAK → COSMIC CLERK	procedural synthesizer	music-hall/ vaudeville family + funk rhythmic system + gospel timbre + whispered/full-voice vocal design

The strongest empirical finding

The musical surface varies dramatically while the cognitive attractor remains recognizable.

Across bluegrass, ragtime, gospel-garage, bebop, and funk/music-hall settings, the same recurring conceptual behaviors survive:

- impossible mathematics is handled procedurally;
- bureaucratic narration suppresses awe;
- language degrades or aliases;
- sensory systems detect abstract structural anomalies;
- manic happiness is expressed through increasingly incompatible musical mechanisms.

That means the system is successfully separating **thought identity** from **genre identity**.

That is exactly what makes the Little Guys useful.

21. A Second Finding: Stack Order Changes the Center of Gravity

When COSMIC CLERK is primary, the songs tend to establish the world through administrative narration and let lossy language and alien sensing mutate it.

When JPEG BRAIN moves into the first position, damaged representation becomes the foundation and bureaucratic language becomes one of the pressures acting on that damaged world.

The difference is conceptually meaningful even when the same three Guys are present.

This validates the decision to treat stack order as non-commutative:

$A \rightarrow B \rightarrow C$ is not the same system as $C \rightarrow B \rightarrow A$.

That alone multiplies the conceptual search space far beyond the raw number of available Guys.

22. A Third Finding: Artistic Quality and Constraint Compliance Are Currently Different Strengths

The model-generated examples often produce more specific, funny, song-like material, but they frequently miss strict character targets.

Examples from the supplied runs include:

- style lengths of 950, 972, 1001, and 1036 instead of 975–999;
- lyric lengths of roughly 2197, 2534, 2802, and 4183 instead of 4900–4999;
- captions that can land far under or slightly over the requested range.

The procedural-synthesizer sample hits **999 / 4999 / 499** exactly within the target windows.

So the current architecture contains a real tradeoff:

LLM path: higher emergent specificity and verbal surprise.
Procedural path: higher formal reliability and dimensional control.

That suggests a strong future architecture would use the procedural system not as a replacement for the model, but as a **structural skeleton or post-generation validator** that preserves the model’s best material while enforcing formal constraints.

23. Where the Little Guys Came From: Temporary Minds

The uploaded *Temporary Minds — 26 Standalone Cognitive Installation Prompts* library reveals a deeper conceptual ancestry.

A substantial portion of the Little Guy collection is a compressed, music-oriented embodiment of those cognitive installations.

Direct or near-direct correspondences include:

Little Guy	Temporary Minds mechanism
PROPERTY THIEF	Property Unbundling / Ownership Transfer
TAXONOMY GOBLIN	Error Axiomatization / Shadow Taxonomy
HOLE GUY	Primitive Deletion / Constitutive Vacuum
FUTURE BASTARD	Teleological Bootstrap Inversion
IDENTITY ACCIDENT	Oneiric Contamination / Identity Slippage
SENSORY FREAK	Synthetic Transducer Array / Downstream Umwelt
EMOTION CRYPTID	Synthetic Valence Topology / Invented Emotion
JPEG BRAIN	Lossy Cognition / Forced Aliasing
RECALL MOLD	Recall Mutation / Reconstructive Memory
RETCON RAT	Semantic Recoil / Interpreter State Mutation

CONFIDENT MACHINE is closely related to structured-error reasoning but specializes it into one coherent false premise.

COSMIC CLERK and OBSERVATION LOG behave more like custom performance/narration mechanisms built in the same spirit.

This matters because the current app does **not** exhaust the source library.

There is still a large reserve of cognitive machinery that can be translated into music.

24. Unused Cognitive Machinery With High Musical Potential

The source library contains several mechanisms that do not yet appear as direct Little Guys. These are especially useful feedstock for a second-generation “weird guy.”

AXIOM FRACTURE / NEGATIVE LOAD-BEARING SYNTHESIS

Find the assumption normally required for musical success, negate it, and require the negation itself to create the success.

Musical example: if ensemble coherence is assumed to require shared pulse, create coherence specifically because shared pulse is impossible.

ATTENTIONAL SHADOW HARVESTING

Stop elaborating the obvious center. Promote a hidden dependency, residue, maintenance cost, absence, or discarded process until it becomes the composition’s governing condition.

Musical example: compose from what musicians normally suppress between notes rather than from the notes.

DESTRUCTIVE COMPRESSION + ALIEN SUBSTRATE TRANSFERENCE

Strip a musical problem down to a minimum causal machine, solve the abstract machine in an unrelated system, then bring back only the structural solution.

This could generate radically new formal architectures without importing themed imagery.

KINETIC DISSOLUTION / METABOLIC VECTOR REORGANIZATION

Treat musical objects as processes maintained by flows, rates, gradients, feedback, and permeability.

Instead of “change the chord,” change the rate at which harmonic identity can repair itself.

OMISSION-FIELD COGNITION

Forbid direct representation of the target and triangulate it through several independent consequences.

A song about grief would never name, symbolize, or conventionally evoke grief; it would generate from independent temporal, bodily, resource, and attentional distortions whose intersection implies it.

CYBERNETIC CIRCUIT CLOSURE

Treat a musical “problem” as one node in a recursive feedback loop and change the relational rule that keeps recreating it.

This is extremely promising for evolving arrangement systems.

ONTOLOGICAL DECOMPILE + CASCADING RECOMPILE

Replace one low-level musical primitive, then rederive every concept that depended on it.

Replace “note” with another primitive and ask what melody, harmony, chord, ornament, and cadence become afterward.

SYSTEMIC TAXONOMIC CONTAGION

Import a foreign lifecycle or rule-system into the composition and make the host genuinely depend on its mechanics.

Import rules, not imagery.

ASYNCHRONOUS MULTI-AXIAL SHEAR

Generate incompatible readings through independent perceptual axes. Make the most anomalous legitimate reading sovereign; let the others become constraints.

This is a natural extension of separate musical jurisdictions.

ALIEN DISTANCE METRICS

Redefine what counts as “similar music” using failure behavior, maintenance burden, residue, collapse trajectory, or another explicit metric.

This could massively improve anti-monoculture selection.

SELECTIVE COGNITIVE LESION

Remove one ordinary operation from the composer and force a prosthetic method to emerge.

Forbid comparison, repetition, segmentation, prediction, or another compositional faculty and see what compensatory grammar appears.

PROCEDURAL TABOO + AFTERMATH CALCULUS

Forbid the direct route to a desired musical effect. The desired outcome may occur only as a side effect of another independently valid process.

ALIEN UTILITY FUNCTION

Separate validity from desirability. Generate valid tracks, but choose among them according to an explicit non-human value function.

DESCENDANT FITNESS / PROGENY SELECTION

Do not choose the best current musical idea. Breed each idea forward and choose the ancestor whose descendants produce the richest territory.

OBSERVATIONAL CRYSTALLIZATION

Every property becomes fixed once it receives deliberate attention. Leave some dimensions unresolved so they retain mutation freedom.

META-GENOMIC SPECIATION

Breed cognitive rules themselves. Do not stack two rules. Construct one irreducible offspring rule that neither parent could produce alone, use it, then let its output change the fitness landscape for the next generation.

This last one is probably the deepest expansion path because it converts the current Little Guy zoo from a fixed menu into an **evolving ecology of composition laws**.

25. The Deeper “Thinking Style” of the Machine

Across the code, the prompts, and the outputs, several recurring philosophical commitments appear.

25.1 Creativity is treated as causal engineering

A strange feature is only valuable if removing it changes what can happen.

25.2 Difference should occur across dimensions, not merely within one style axis

The machine prefers harmonic contradiction against rhythmic stability, semantic mutation against phonetic continuity, or temporal mismatch against invariant contour.

25.3 Contradictions should negotiate, not dissolve

The system does not seek synthesis too early.

25.4 Mutation needs memory

Without an anchor or remembered earlier state, change cannot be measured.

25.5 Repetition should accumulate history

A returning object should carry scars.

25.6 Attention is a resource

Different Guys control attention, observation, memory, narration, and ontology separately.

25.7 “Genre” is too coarse to be the main unit

Composition is represented as a vector across independent systems.

25.8 The system values rules that survive translation

A good cognitive mechanism should still work if its theatrical vocabulary is stripped away.

25.9 Weirdness is strongest when the premise is bizarre and the deductions are disciplined

The engine repeatedly prefers one impossible law followed rigorously over a pile of random surreal nouns.

25.10 The machine is secretly obsessed with load-bearing structure

Again and again it asks: what can be removed, transferred, inverted, damaged, or misclassified **without making the whole thing arbitrary?**

26. What a “Weird Guy” Should Steal From This

Do not steal the genres.

Do not steal the phrases.

Do not even necessarily steal the existing Little Guys.

Steal the **architecture of thought**:

A. Build generators from operators, not adjectives

“Make it stranger” is weak.

“Each recurrence loses one representational dimension while retaining rhythmic identity” is strong.

B. Separate jurisdictions

If two rules can both freely alter everything, they blur. Give each one sovereignty over a different variable.

C. Make order non-commutative

Rule A as foundation plus B as mutator should not equal B as foundation plus A as mutator.

D. Track negative and positive memory separately

Avoid recently occupied territory while also learning mechanisms the user liked.

E. Preserve one invariant

Novelty becomes more legible when something survives it.

F. Breed rules, not merely outputs

The next stage is not “more Little Guys.” It is machinery that invents new Guys by combining underlying operations into irreducible offspring.

G. Change the ruler

Novelty detection should periodically replace its own similarity metric so that “different” does not become predictable.

H. Make consequences cross modalities

If a cognitive law changes semantics, ask what rhythmic, melodic, timbral, performance, and production consequences are forced by that semantic mutation.

I. Use formal failure productively

Length failure, memory degradation, tuning drift, syntax aliasing, timing mismatch, and lost information can all become compositional mechanisms rather than errors to hide.

J. Let the output change the generator

After each successful song, the system should ask what territory is now exhausted, what new dependency appeared, and which cognitive rule has become too predictable.

27. A Compact Model of the Entire Machine

The current engine can be reduced to this pipeline:

SEED / SUBJECT

↓

CHOOSE COGNITIVE FOUNDATION

↓

ADD ORTHOGONAL MUTATORS BY JURISDICTION

↓

CHOOSE A DIVERSE MUSICAL FINGERPRINT ACROSS 8 AXES

↓

DEFINE AN ANCHOR / INVARIANT

↓

INVENT TRANSFORMATION OPERATORS

↓

ESTABLISH FORM

↓

DESTABILIZE JURISDICTIONS

↓

FRACTURE TEMPORAL / STRUCTURAL AGREEMENT

↓

REMOVE SUPPORT / COLLAPSE

↓

RETURN THE ANCHOR WITH A SCAR

↓

REFORM WITHOUT RESETTING

↓

RECORD THE MUSICAL FINGERPRINT

↓

USE RECENT RUNS AS ANTI-MONOCULTURE MEMORY

↓

USE STARRED RUNS AS MECHANISM-LEVEL POSITIVE MEMORY

↓

NEXT RUN OCCURS IN A CHANGED CREATIVE LANDSCAPE

That final loop is the beginning of something much larger than a prompt randomizer.

It is the beginning of a **small evolutionary composition system**.

28. Current Weak Spots / Opportunities

The machine is already unusually coherent, but an audit should include the places where more weirdness can be extracted.

Static taxonomy

The musical library is broad but finite. Over enough runs, its vocabulary will become recognizable.

Opportunity: make taxonomy expansion itself generative. When a category is repeatedly selected, split it into more precise mechanisms or retire it temporarily.

Weak explicit cross-jurisdiction propagation

The prompt says systems must negotiate, but it does not always specify how a change in one jurisdiction forces consequences in another.

Opportunity: install causal bridges. Example: when semantic certainty decreases, consonant density must increase; when rhythmic debt exceeds a threshold, harmonic resolution is postponed.

Anti-monoculture currently operates mostly by textual similarity

The procedural chooser penalizes recently used phrases. This prevents simple repetition but does not yet measure deeper structural sameness.

Opportunity: introduce rotating alien distance metrics: similarity by collapse trajectory, density profile, anchor behavior, ensemble topology, entropy curve, or information-loss pattern.

Positive feedback is useful but still shallow

The app stores what was starred and optional user notes, then asks the model to infer the liked principle.

Opportunity: extract explicit mechanism tags from feedback: “liked because the chorus did not reset,” “liked the dry narrator against ecstatic choir,” “liked rhythm remaining stable while harmony degraded.”

Model outputs often fail strict dimensional constraints

The supplied runs show major under-length lyrics.

Opportunity: generate creatively first, then use a structure-aware expansion engine that adds new transformations rather than padding.

Procedural output can become too self-explanatory

The fallback sometimes names the Little Guys and explains the mechanism directly.

Opportunity: preserve the mechanism but hide the machinery. Convert each meta-instruction into an audible event.

29. Suggested Prompt for the Next “Weird Guy”

The following is not a replacement for the paper. It is a compact instruction distilled from the audit:

Study the Little Guy Machine as a generator of causal composition laws, not as a collection of musical styles. Identify its underlying operations: separate jurisdictions, ordered primary/mutator stacks, invariants, scarred recurrence, anti-monoculture memory, mechanism-level preference memory, phonetic embodiment, structural collapse, and reform without reset. Then invent NEW composition procedures that are not simple variations of those already present. Prefer operations that change what can be selected, remembered, compared, repeated, sensed, valued, or causally connected. Do not propose “genre blends.” For each new mechanism, specify: the variable it governs; what ordinary assumption it removes or changes; its exact transformation rule; what remains invariant; how the rule propagates into harmony, melody, rhythm, timbre, voice, performance, or production; how to tell whether the mechanism is genuinely load-bearing; and what new territory it opens. Periodically

change the metric by which novelty itself is judged. When combining mechanisms, breed one irreducible new rule rather than merely stacking them. The goal is not more weird content. The goal is new ways for music to become weird.

30. Conclusion

The Little Guy Machine works because it does something most creative prompt systems do not:

it has a theory of where novelty should live.

Novelty does not need to live in every variable simultaneously.

One thing can remain fixed while another migrates.

One cognitive rule can define reality while another damages memory.

A vocal line can stretch while rhythm compresses.

A chorus can return while its meaning changes.

A genre can disappear entirely while the cognitive law survives.

That is why the supplied tracks can jump from bluegrass to ragtime to gospel-garage to bebop and still feel like products of the same strange intelligence.

The real reusable object is therefore not any individual prompt.

It is the **negotiation architecture**:

define independent systems – assign jurisdiction – create conflict – preserve an invariant – propagate consequences – return with scars – remember the territory – mutate the rules themselves.

That is the shit worth feeding to the next machine.
