

READ THE ATTACHED “LITTLE GUY MACHINE — COGNITIVE-COMPOSITION AUDIT” FIRST.

Treat that document as KNOWN TERRITORY.

I do NOT want you to merely invent additional Little Guys, swap genres, rename existing operators, or recombine mechanisms already described in the paper.

Your job is to discover NEW WAYS TO FUCK WITH SUNO.

Think like an experimental composer, systems theorist, mischievous audio engineer, linguist, information theorist, producer, cognitive scientist, glitch artist, game designer, mathematician, and someone who has just been handed a strange musical machine and wants to find every non-obvious handle on it.

The question is:

WHAT VARIABLES, CONTROL SURFACES, FAILURE MODES, REPRESENTATIONS, TEMPORAL RELATIONSHIPS, FEEDBACK LOOPS, AND MULTI-PASS PROCEDURES HAVE WE NOT YET THOUGHT TO MANIPULATE?

Do not assume “prompting Suno” means describing a finished song.

Treat Suno as a SYSTEM WE CAN INTERACT WITH.

Look for ways to manipulate:

- what information Suno receives
- when it receives information
- which information remains constant
- which information is deliberately missing
- contradictions between instructions
- instruction priority
- repetition and recurrence
- temporal scale
- lyric syntax
- phonetics
- vocal articulation
- silence
- arrangement density
- perceived causality
- musical expectation
- transitions
- section boundaries

- instrumentation roles
- harmony
- melody
- rhythm
- meter
- tempo
- tuning
- production space
- performer behavior
- semantic meaning
- narrative viewpoint
- memory across sections
- motif identity
- degradation
- reconstruction
- continuation
- regeneration
- alternate versions
- stem-level transformations
- section replacement
- editing passes
- iterative prompting
- outputs used as future inputs
- interactions between generations
- human selection between passes
- deliberate model misunderstanding
- controlled ambiguity
- information bottlenecks
- lossy translation
- over-specification
- under-specification
- parameter drift
- recursive processes
- emergent behavior
- anything else you discover

IMPORTANT:

Do not assume every useful manipulation belongs INSIDE THE INITIAL PROMPT.

Some experiments may operate:

BEFORE generation

DURING conceptual construction

BETWEEN multiple generations
ON A GENERATED SONG
ON INDIVIDUAL STEMS
THROUGH EDIT / REPLACE / CONTINUE / REMIX-LIKE WORKFLOWS
THROUGH LYRIC REPLACEMENT
THROUGH SUCCESSIVE TRANSFORMATIONS
THROUGH HUMAN SELECTION
THROUGH FEEDBACK FROM PREVIOUS RESULTS

Only use Suno features that actually exist or that I tell you are available. If uncertain about a specific product feature, describe the operation abstractly instead of inventing a button.

I want MECHANISMS, not aesthetics.

BAD:

“Combine polka, doom metal, and throat singing.”

GOOD:

“Generate a stable rhythmic object, then in successive passes preserve only its attack-time topology while forcing every audible sound source to change category.”

BAD:

“Make the song increasingly insane.”

GOOD:

“Every 16 bars, remove one piece of information required to reconstruct the opening motif. The composition must continue reconstructing it from the incomplete remainder.”

BAD:

“Use glitch effects.”

GOOD:

“Treat errors from one generation as protected invariants and regenerate everything except the errors.”

STRANGENESS MUST DO WORK.

=====
PHASE 1 — MAP THE KNOWN TERRITORY
=====

From the attached audit, briefly identify the major mechanism families we ALREADY USE.

Examples include things like:

separate jurisdictions
primary + mutator stacks
property transfer
primitive deletion
lossy cognition
wrong classification
reverse causality
semantic recoil
reconstructive memory
alien sensing
invented affect
literal identity collision
coherent false premises
scarred recurrence
anchors/invariants
anti-monoculture memory
phonetic engines
FORM → DESTABILIZE → FRACTURE → COLLAPSE → RETURN → REFORM
productive contradiction

Do not spend much time explaining these.

Their purpose is to create an EXCLUSION MAP.

Then ask:

WHAT IS NOT ON THIS MAP?

=====
PHASE 2 — SEARCH FOR NEW CONTROL DIMENSIONS
=====

Find conceptual axes we have barely touched or not touched at all.

Search broadly across fields such as:

information theory
control theory
cybernetics
dynamical systems
evolution
developmental biology
ecology

linguistics
phonology
psychophysics
perception
memory
distributed systems
error-correcting codes
compression
cryptography
signal processing
topology
graph theory
game theory
economics
queueing theory
thermodynamics
fluid dynamics
statistical mechanics
computation
programming language design
type systems
network protocols
fault tolerance
adversarial examples
measurement theory
experimental music
orchestration
improvisation
theater
ritual
conversation
collective behavior
anything else structurally useful

IMPORT RULES, NOT DECORATION.

I do not want “a song themed around quantum mechanics.”

I want something like:

“A musical state may only change when two independently generated descriptions of that state disagree.”

That is an OPERATION.

=====

PHASE 3 — FIND NEW PLACES TO INTERVENE

=====

Most prompt systems intervene at the level of CONTENT.

Do not stop there.

Investigate interventions at:

REPRESENTATION

What form is the instruction encoded in?

SELECTION

How are candidate outputs chosen?

SEQUENCE

In what order are transformations applied?

MEMORY

What survives between passes?

LOSS

What information is intentionally destroyed?

ERROR

Which mistakes become protected?

OBSERVATION

Does measuring or describing something freeze it or change it?

FEEDBACK

Can an output alter the rules generating its successor?

SCALE

Can one process operate every beat while another changes only once per song?

BOUNDARIES

Who decides where a section, instrument, phrase, or identity begins and ends?

OWNERSHIP

Which musical layer has authority over a property?

TRANSLATION

What happens when the same structure is repeatedly translated between musical representations?

COMPETITION

Can multiple valid interpretations fight for limited musical resources?

RESOURCE ALLOCATION

What if notes, words, beats, registers, instruments, consonants, harmonic tension, or silence have budgets?

LATENCY

What if consequences are delayed?

DEBT

What if unresolved events accumulate obligations that must later be paid?

ERROR CORRECTION

What information can be corrupted while still allowing a motif to remain recognizable?

INHERITANCE

What can a regenerated section inherit from its ancestor besides obvious melody?

FITNESS

Can we select a mediocre present version because its descendants become more interesting?

PATH DEPENDENCE

Can identical instructions create different results solely because they arrived through different histories?

=====

PHASE 4 — FUCK WITH THE GENERATION PROCESS ITSELF

=====

Invent experiments involving multiple Suno generations.

Do not assume:

PROMPT → SONG → DONE.

Consider chains such as:

PROMPT
→ GENERATE

- EXTRACT ONE PROPERTY
- DESTROY ANOTHER
- REGENERATE
- SELECT AN ERROR
- MAKE ERROR INVARIANT
- REBUILD
- REPEAT

Explore procedures where:

a child song inherits only one structural property from each parent

a later version is prohibited from accessing the original prompt

each pass receives a damaged description of the previous pass

only disagreements between two versions survive into generation three

the least successful section becomes the seed for the next track

one stem becomes the clock that all other stems must misinterpret

lyrics are rewritten according to acoustic events from the previous rendering

the semantic description and actual audio evolve separately

a regenerated section must preserve something the listener notices but the prompt never names

the song gradually develops its own rules from earlier generation artifacts

human preference changes the mutation operator rather than simply picking the favorite song

These are EXAMPLES OF THE LEVEL OF THINKING, not ideas to merely repeat.

Go substantially farther.

=====

PHASE 5 — SUNO MISBEHAVIOR AS MATERIAL

=====

Investigate productive use of model tendencies and failures.

Ask:

What does Suno misunderstand consistently?

What does it average together?

What does it exaggerate?

What does it ignore?

What does it unexpectedly preserve?

What instructions produce side effects?

What happens when structural instructions disagree without being mutually exclusive?

Can unwanted artifacts become anchors?

Can a failed vocal interpretation become a rhythmic control signal?

Can pronunciation errors breed a new phonetic language?

Can section-transition mistakes become formal rules?

Can genre misclassification be harvested?

Can generations be selected specifically because they failed in DIFFERENT ways?

Do not merely seek “bugs.”

Look for REPEATABLE BEHAVIORS that can become compositional machinery.

=====

PHASE 6 — INVENT NEW MUSICAL OPERATORS

=====

Create genuinely new operators.

Each operator must have:

NAME

TARGET VARIABLE

INPUT STATE

TRANSFORMATION

WHAT REMAINS INVARIANT

WHAT CONSEQUENCE PROPAGATES ELSEWHERE

WHY THIS IS NOT ALREADY COVERED BY THE LITTLE GUY SYSTEM

HOW TO TEST IT IN SUNO

WHAT FAILURE WOULD TEACH US

ONE MUTATION OF THE OPERATOR

Avoid generic operators such as:

- randomize
- make stranger
- add complexity
- switch genre
- increase chaos
- distort everything
- be experimental

Operators should be executable ideas.

=====
PHASE 7 — INVENT MULTI-PASS EXPERIMENTS
=====

Design at least 20 experiments.

Spread them across very different intervention surfaces.

Do NOT give me twenty lyric tricks.

I want experiments involving different combinations of:

- composition
- prompt structure
- phonetics
- arrangement
- form

stems
regeneration
editing
continuation
selection
memory
feedback
loss
recursion
inheritance
production
human intervention
model error
cross-generation processes

For every experiment provide:

TITLE

CORE MECHANISM

WHY IT IS DIFFERENT FROM WHAT WE ALREADY DO

FIRST SUNO EXPERIMENT

WHAT TO LISTEN FOR

WHAT TO DO ON PASS TWO

HOW IT COULD MUTATE IF SUCCESSFUL

Keep each concise enough that I can actually try it.

=====
PHASE 8 — FIND THE REALLY FUCKED-UP ONES
=====

After generating the sensible experimental ideas, assume they are still too conventional.

Perform a second search.

Ask:

“What assumption about interacting with a music generator did every previous idea quietly preserve?”

Remove that assumption.

Then give me 10 WILDCARD mechanisms.

These should make me say:

“Wait. Can we even do that?”

But they must remain operational enough to test.

Surprise caused purely by absurd vocabulary DOES NOT COUNT.

=====
PHASE 9 — BREED THE BEST NEW RULES
=====

Choose several of the strongest mechanisms you discovered.

Do NOT simply stack them.

Breed pairs into one new irreducible operator.

For each offspring:

PARENT A
PARENT B
OFFSPRING LAW
WHY A ALONE CANNOT PRODUCE IT
WHY B ALONE CANNOT PRODUCE IT
WHAT NEW MUSICAL TERRITORY IT OPENS

Kill offspring that are merely A followed by B.

=====
PHASE 10 — BUILD ME A NEW MAP
=====

End by constructing a taxonomy called:

NEW WAYS TO FUCK WITH SUNO

Do not organize it by genre.

Organize it by WHERE THE INTERVENTION OCCURS.

For example, your categories might emerge around:

representation
generation history
memory
error
time
selection
stems
causality
information
feedback
identity
performance
human/model interaction

But do not force those categories if you discover better ones.

For each family, tell me:

WHAT IT MANIPULATES
WHY IT IS DISTINCT
WHAT WE HAVE NOT EXPLORED YET
THE MOST PROMISING FIRST EXPERIMENT

FINAL PRINCIPLE:

I am not looking for stranger SONG IDEAS.

I am looking for stranger WAYS OF USING THE MACHINE.

Do not decorate Suno.

FUCK WITH ITS CAUSAL STRUCTURE.
